**VM ARCHITECTURE:** Java Virtual machine.

VM is an abstract machine.

Provides runtime environment in which bytecode can be executed.

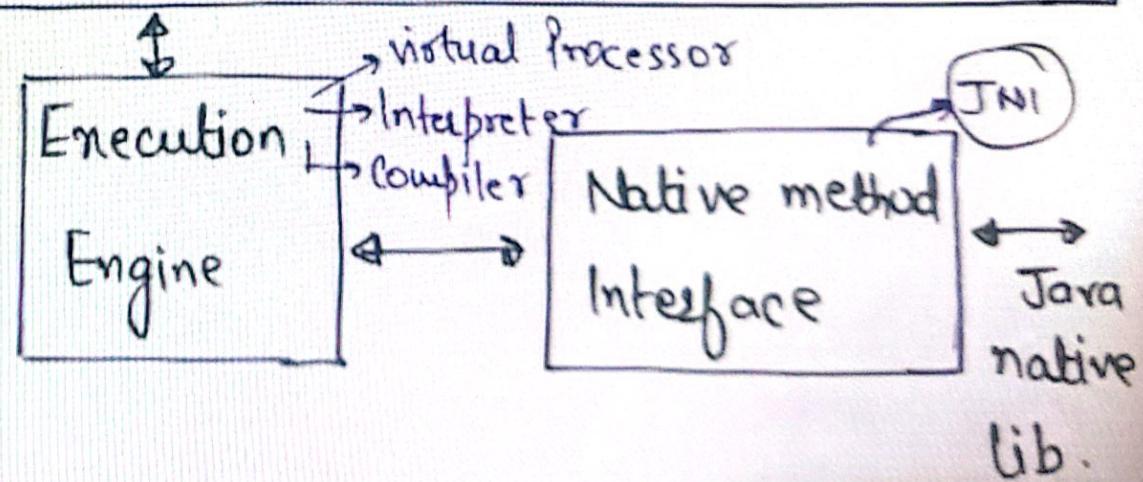

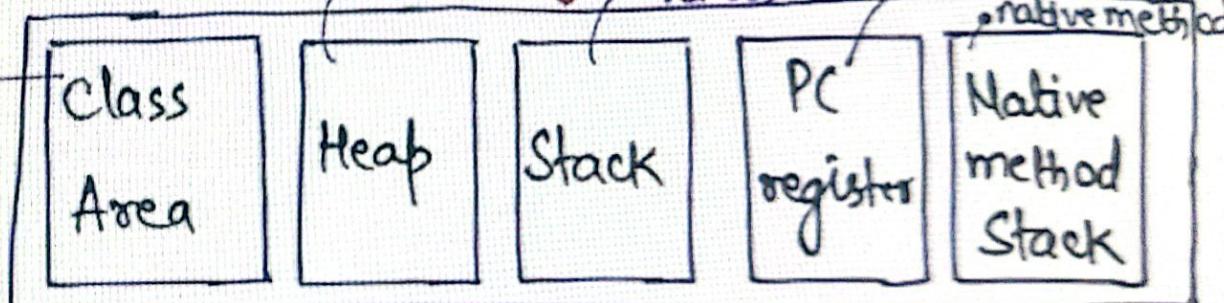

Operations performed by JVM:

- ↳ Loads the code
- ↳ verifies the code
- ↳ Executes the code (runtime const.)
- ↳ Provides Runtime Env. Pool

PC reg. → Stores address of currently executing instruction

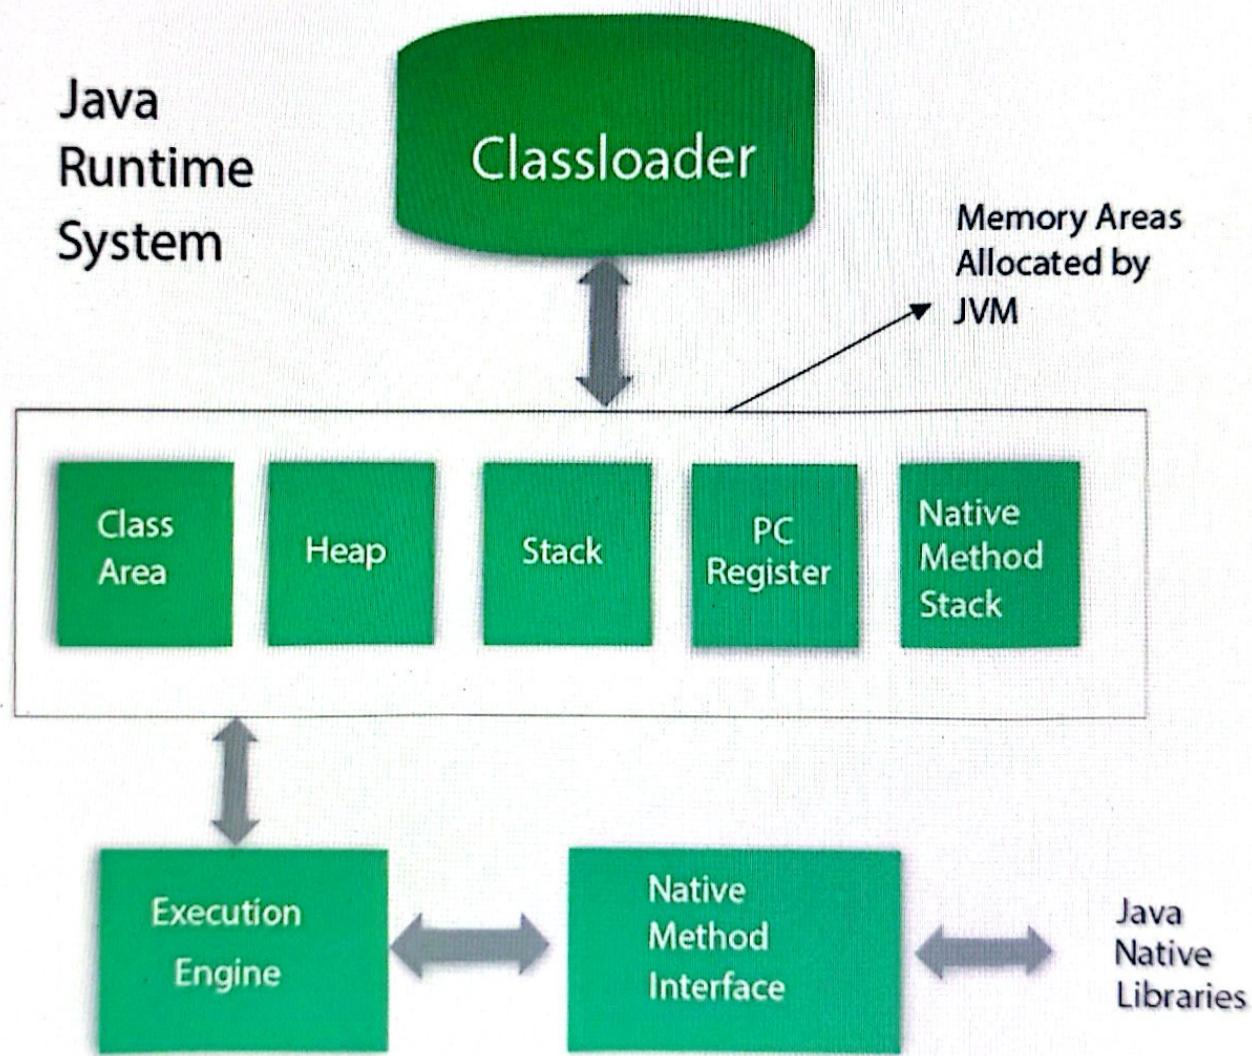

by JVM.

Java runtime System

## JVM Architecture

Let's understand the internal architecture of JVM. It contains classloader, memory area, execution engine etc.

### 1) Classloader

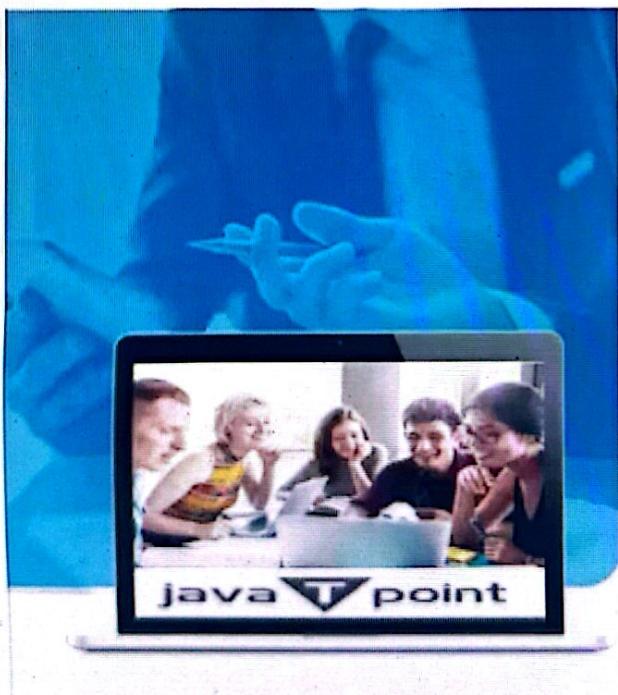

Classloader is a subsystem of JVM which is used to load class files. Whenever we run the java program, it is

## What is Java?

Java is a **programming language** and a **platform**. Java is a high level, robust, object-oriented and secure programming language.

Java was developed by *Sun Microsystems* (which is now the subsidiary of Oracle) in the year 1995. James Gosling is known as the father of Java. Before Java, its name was Oak. Since Oak was already a registered company, so James Gosling and his team changed the name from Oak to Java.

**Platform:** Any hardware or software environment in which a program runs, is known as a platform. Since Java has a runtime environment (JRE) and API, it is called a platform.

STACK *using Array*

## Java Example

Let's have a quick look at Java programming example. A detailed description of Hello Java example is available in next page.

### Simple.java

```
class Simple{  
    public static void main(String args[]){  
        System.out.println("Hello Java");  
    }  
}
```

 Test it Now

## Application

According to Sun, 3 billion devices run Java. There are many devices where Java is currently used. Some of them are as follows:

1. Desktop Applications such as acrobat reader, media player, antivirus, etc.
2. Web Applications such as irctc.co.in, javatpoint.com, etc.
3. Enterprise Applications such as banking applications.
4. Mobile
5. Embedded System
6. Smart Card
7. Robotics
8. Games, etc.

# Objects and Classes in Java

[← Prev](#)[Next →](#)

In this page, we will learn about Java objects and classes. In object-oriented programming technique, we design a program using objects and classes.

An object in Java is the physical as well as a logical entity, whereas, a class in Java is a logical entity only.

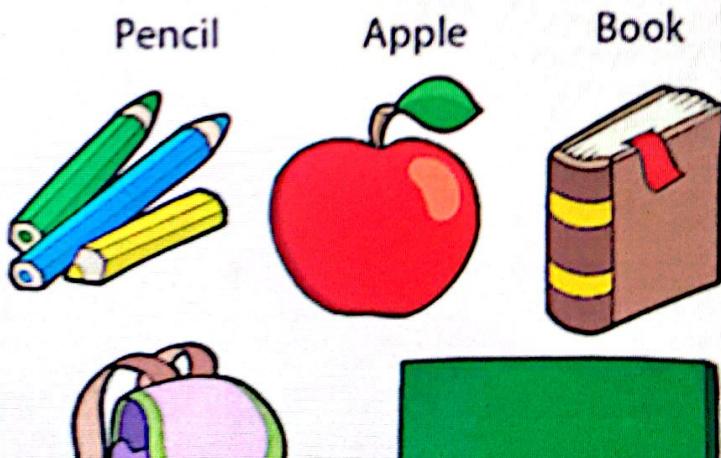

## What is an object in Java

An entity that has state and behavior is known as an object e.g., chair, bike, marker, pen, table, car, etc. It can be physical or logical (tangible and intangible). The example of an intangible object is the banking system.

An object has three characteristics:

- Object in Java
- Class in Java
- Instance Variable in Java
- Method in Java
- Example of Object and class that maintains the records of student
- Anonymous Object

## Objects: Real World Examples

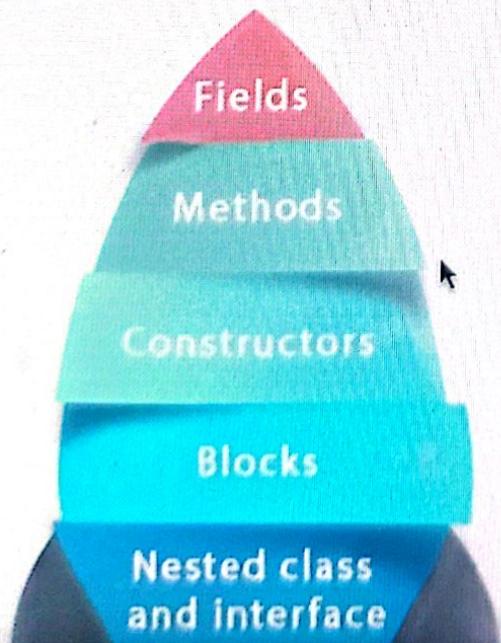

## What is a class in Java

A class is a group of objects which have common properties. It is a template or blueprint from which objects are created. It is a logical entity. It can't be physical.

A class in Java can contain:

- **Fields**
- **Methods**
- **Constructors**
- **Blocks**
- **Nested class and interface**

## Class in Java

# Constructors in Java

In Java, a constructor is a block of codes similar to the method. It is called when an instance of the class is created. At the time of calling constructor, memory for the object is allocated in the memory.

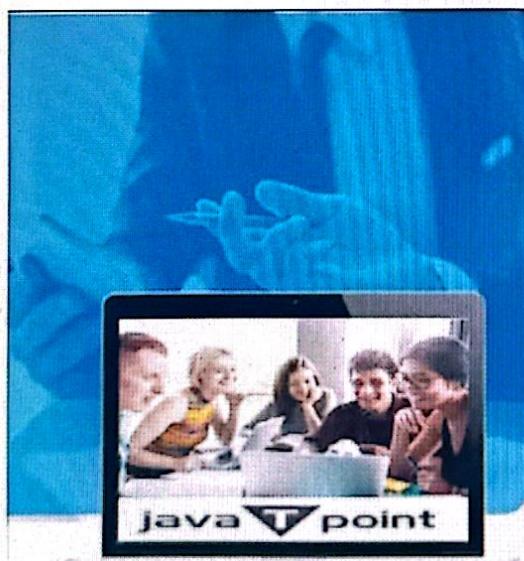

It is a special type of method which is used to initialize the object.

Every time an object is created using the new() keyword, at least one constructor is called.

It calls a default constructor if there is no constructor available in the class. In such case, Java compiler provides a default constructor by default.

## Types of constructors

- Default Constructor
- Parameterized Constructor
- Constructor Overloading
- Does constructor return any value?
- Copying the values of one object into another
- Does constructor perform other tasks instead of the initialization

java T point

## STACK IN DS

C PROGRAM TO IMPLEMENT  
STACK

There are two types of constructors in Java: no-arg constructor, and parameterized constructor.

**Note:** It is called constructor because it constructs the values at the time of object creation. It is not necessary to write a constructor for a class. It is because java compiler creates a default constructor if your class doesn't have any.

## Rules for creating Java constructor

There are two rules defined for the constructor.

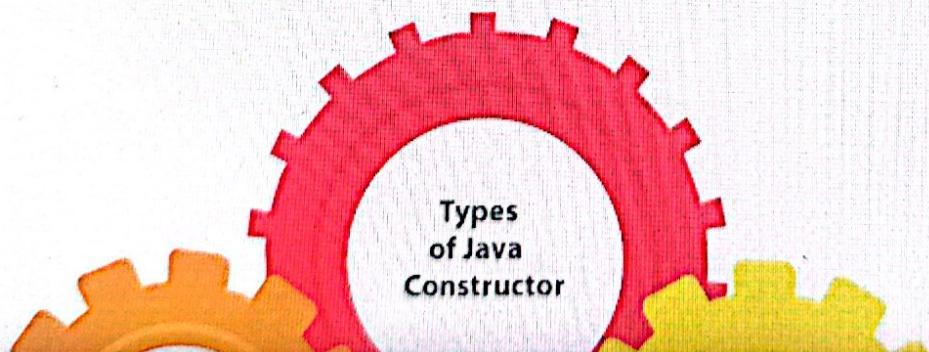

1. Constructor name must be the same as its class name
2. A Constructor must have no explicit return type
3. A Java constructor cannot be abstract, static, final, and synchronized

 Note: We can use access modifiers while declaring a constructor. It controls the object creation. In other words, we can have private, protected, public or default constructor in Java.

## Types of Java constructors

There are two types of constructors in Java:

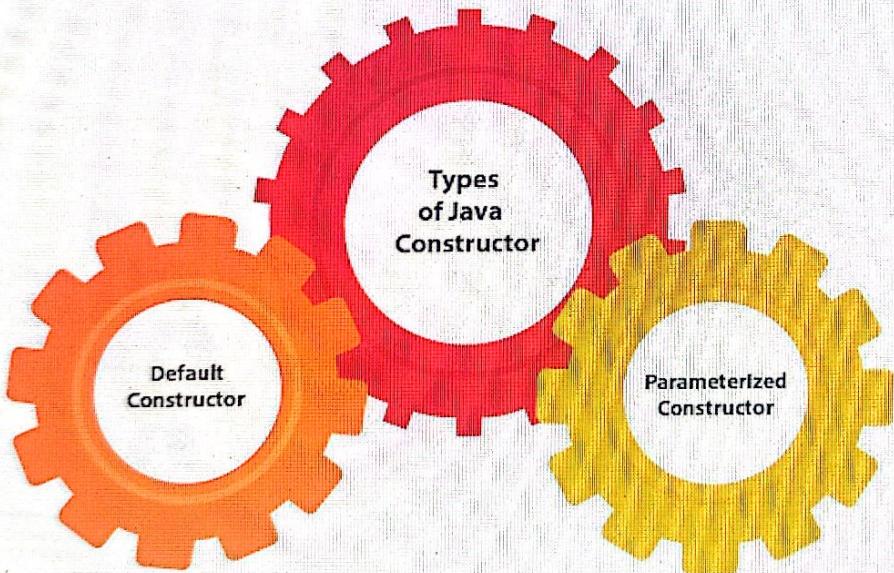

1. Default constructor (no-arg constructor)
2. Parameterized constructor

# Types of Java constructors

There are two types of constructors in Java:

1. Default constructor (no-arg constructor)
2. Parameterized constructor

## Java Default Constructor

A constructor is called "Default Constructor" when it doesn't have any parameter.

Syntax of default constructor:

```
<class_name>(){}
```

Example of default constructor

CPI

```
gasoline max 1  
void push();  
void push();  
void pop();  
int st(max);  
int sup(-1);  
void main()
```

```
{  
    int ch;  
    ch=ch+1;  
    write(ch);  
}
```

```
print  
print  
print  
print
```

## Example of default constructor

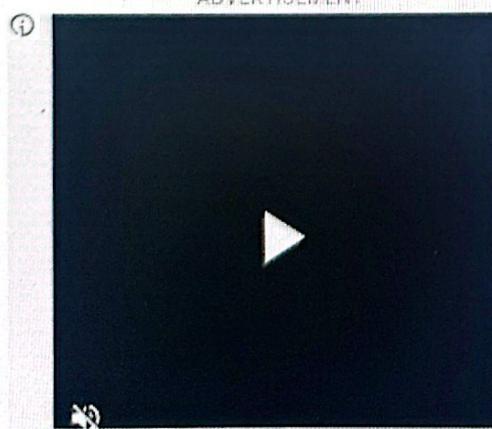

In this example, we are creating the no-arg constructor in the Bike class. It will be invoked at the time of object creation.

```
//Java Program to create and call a default constructor  
class Bike1{  
    //creating a default constructor  
    Bike1(){System.out.println("Bike is created");}  
    //main method  
    public static void main(String args[]){  
        //calling a default constructor  
        Bike1 b=new Bike1();  
    }  
}
```

## Example of parameterized constructor

In this example, we have created the constructor of Student class that have two parameters. We can have any number of parameters in the constructor.

```
//Java Program to demonstrate the use of the parameterized constructor.
```

```
class Student4{  
    int id;  
    String name;  
    //creating a parameterized constructor  
    Student4(int i, String n){  
        id = i;  
        name = n;  
    }  
    //method to display the values  
    void display(){System.out.println(id+" "+name);}  
  
    public static void main(String args[]){  
        //creating objects and passing values  
        Student4 s1 = new Student4(111, "Karan");  
        Student4 s2 = new Student4(222, "Aryan");  
        //calling method to display the values of object  
        s1.display();  
        s2.display();  
    }  
}
```
